evaluation, book, tutorials

what	when	how much
midterm 1	2017-02-13	25%
midterm 2	2017-03-27	25%
exam	TBA	50%

I will suggest exercises from the "required" book:

de Veaux, et al., 2014. *Stats: Data and Models*, Second Canadian Edition, 2 edition. ed. Pearson Canada.

Some suggested exercises will be worked out in tutorial each week, starting TBA.

Not a terrible book. I agree with most of it. Too many words. But covers what we need.

Any thick and comprehensive "Stats 101" book could also be a good resource.

software

Data analysis requires a computer. Also, some concepts can be illustrated using simulation, which also requires a computer. We will be using R. It's pretty good at data analysis.

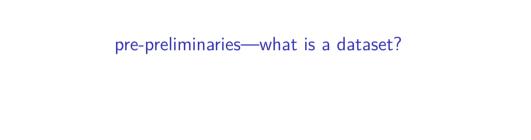

language	interpreter	integrated development environment
R	R	RStudio

Some detailed instructions and suggestions for installation and configuration appear on the course website. I will try to impart some data analysis workflow wisdom throughout the course. Some already appears in the detailed instructions.

I have signed up STA221 to have access to some optional R courses on the (well-regarded) datacamp.com training company.

A higher level but thorough resource is:

Grolemund, G., Wickham, H., R for Data Science **available free at http://r4ds.had.co.nz/**

most datasets are rectangles

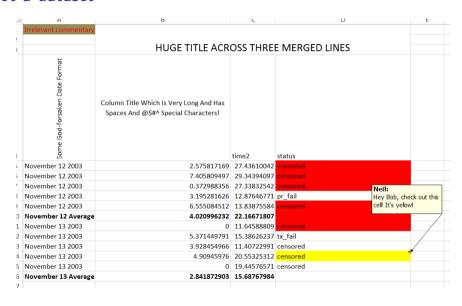

Columns are the variables.

The top row has the names of the variables; possibly chosen wisely.

Rows are the observations of measurements taken on units.

There are no averages, no comments (unless in a "comment" variable), no colors, no formatting, no plots!

not a dataset

not a dataset

▶ where did the data come from?

- ▶ where did the data come from?
 - were the units chosed randomly from a population?

- where did the data come from?
 - were the units chosed randomly from a population?
 - were the units randomly assigned into groups?

- where did the data come from?
 - were the units chosed randomly from a population?
 - were the units randomly assigned into groups?
- what are the (joint) distributions of the data?

Sometimes the data come from a *random sample* from a larger *population*, in which case statements about the sample can apply to the population using laws of probability.

Sometimes the data come from a *random sample* from a larger *population*, in which case statements about the sample can apply to the population using laws of probability. (Not a focus of this course.)

Sometimes the data come from a *random sample* from a larger *population*, in which case statements about the sample can apply to the population using laws of probability.

(Not a focus of this course.)

Sometimes data come from an *experiment* where units are randomly assigned to different *levels* of one or more *factors*, in which cause cause-and-effect can be inferred using laws of probability.

Sometimes the data come from a *random sample* from a larger *population*, in which case statements about the sample can apply to the population using laws of probability.

(Not a focus of this course.)

Sometimes data come from an *experiment* where units are randomly assigned to different *levels* of one or more *factors*, in which cause cause-and-effect can be inferred using laws of probability.

Often the data are just some records of what happened. Grander inferences might be made, but only on a subject-matter basis.

Two events A and B are independent if:

$$P(A \cap B) = P(A)P(B),$$

(where \cap means and.)

For example, roll a fair die. Let $A = \{1, 2, 3\}$ and $B = \{2, 4\}$.

Two events A and B are independent if:

$$P(A \cap B) = P(A)P(B),$$

(where \cap means and.)

For example, roll a fair die. Let $A = \{1, 2, 3\}$ and $B = \{2, 4\}$.

$$P(A) = 1/2$$
 and $P(B) = 1/3$, so $P(A)P(B) = 1/6$.

Two events A and B are independent if:

$$P(A \cap B) = P(A)P(B),$$

(where \cap means and.)

For example, roll a fair die. Let $A = \{1, 2, 3\}$ and $B = \{2, 4\}$.

$$P(A) = 1/2$$
 and $P(B) = 1/3$, so $P(A)P(B) = 1/6$.

Also, $A \cap B = \{2\}$ so $P(A \cap B) = 1/6 = P(A)P(B)$

Two events A and B are independent if:

$$P(A \cap B) = P(A)P(B)$$
,

(where \cap means and.)

For example, roll a fair die. Let $A = \{1, 2, 3\}$ and $B = \{2, 4\}$.

$$P(A) = 1/2$$
 and $P(B) = 1/3$, so $P(A)P(B) = 1/6$.

Also,
$$A \cap B = \{2\}$$
 so $P(A \cap B) = 1/6 = P(A)P(B)$

Conclude: A and B are independent (short form: $A \perp B$.)

Two events A and B are independent if:

$$P(A \cap B) = P(A)P(B)$$
,

(where \cap means and.)

For example, roll a fair die. Let $A = \{1, 2, 3\}$ and $B = \{2, 4\}$.

$$P(A) = 1/2$$
 and $P(B) = 1/3$, so $P(A)P(B) = 1/6$.

Also,
$$A \cap B = \{2\}$$
 so $P(A \cap B) = 1/6 = P(A)P(B)$

Conclude: A and B are independent (short form: $A \perp B$.)

Exercise: if $C = \{2, 5, 6\}$ then $B \perp C$ and $A \not\perp C$ (CORRECTED FROM CLASS)

Independence is normally something that is *assumed* and not something that is demonstrated.

Independence is normally something that is *assumed* and not something that is demonstrated.

Undisciplined use of language (e.g. "A has nothing to do with B") is the leading cause of error. Use the definition.

Independence is normally something that is *assumed* and not something that is demonstrated.

Undisciplined use of language (e.g. "A has nothing to do with B") is the leading cause of error. Use the definition.

The opposite of independent is "not independent." (Avoid "dependent", which has misleading connotations.)

Independence is normally something that is *assumed* and not something that is demonstrated.

Undisciplined use of language (e.g. "A has nothing to do with B") is the leading cause of error. Use the definition.

The opposite of independent is "not independent." (Avoid "dependent", which has misleading connotations.)

$$A \perp B \iff A \perp B^c \iff A^c \perp B \iff A^c \perp B^c$$

concept of random variable

A random variable is a rule that assigns a number to any outcome of a random process.

Example: "Roulette". There are 38 slots on a wheel coloured as follows:

Colour	# of slots	Slot labels
Green	2	0, 00
Red	18	1, 3, 5, 7, 9, 12, 14, 16, 18, 19, 21,
Black	18	23, 25, 27, 30, 32, 34, 36 2, 4, 6, 8, 10, 11, 13, 15, 17, 20, 22, 24, 26, 28, 29, 31, 33, 35

roulette - II

If bet \$100 on "Red", then these are the possibilities:

Result	I receive	
Red	200	
Not Red	0	
- INOL INCU	0	

Stated another way, here is my net "gain", which I will call X, after the play:

Result	Χ
Red	100
Not Red	-100

roulette - III

Technically the random variable is this the *rule*:

$$X(1) = X(3) = X(5) = \cdots = X(36) = 100$$

 $X(00) = X(0) = X(2) = \cdots = X(35) = -100$

roulette - III

Technically the random variable is this the *rule*:

$$X(1) = X(3) = X(5) = \cdots = X(36) = 100$$

 $X(00) = X(0) = X(2) = \cdots = X(35) = -100$

But this is often a useless technicality. This is all we care about:

X	P(X = x)
100	18/38
-100	20/38

This table is the distribution of X, i.e. the possible outcomes and their probabilities.

distribution and independence

The distribution of a random variable X is, roughly, all information about the values of X and their probabilities.

distribution and independence

The distribution of a random variable X is, roughly, all information about the values of X and their probabilities.

There's the odd (or maybe not?) fact that when X is *continuously measured* then we have P(X = x) = 0 for any particular x. In this case we're concerned with intervals of values and not particular values.

distribution and independence

The distribution of a random variable X is, roughly, all information about the values of X and their probabilities.

There's the odd (or maybe not?) fact that when X is *continuously measured* then we have P(X=x)=0 for any particular x. In this case we're concerned with intervals of values and not particular values.

X and Y can be independent when *knowing the outcome of X does not change the distribution of Y - a very strong statement (usually assumed when appropriate.)

$$E(aX + b) = aE(X) + b$$

$$E(aX + b) = aE(X) + b$$

$$E(X + Y) = E(X) + E(Y)$$

$$E(aX + b) = aE(X) + b$$

$$E(X + Y) = E(X) + E(Y)$$

$$Var(aX + b) = a^{2}Var(X)$$

$$E(aX + b) = aE(X) + b$$

 $E(X + Y) = E(X) + E(Y)$
 $Var(aX + b) = a^2Var(X)$
 $Var(X + Y) = Var(X) + Var(Y)$ when $X \perp Y$

normal distributions and the central limit theorem

Normal distributions are an important family of symmetric, bell-shaped distributions, parametrized by mean μ and standard deviation σ .

normal distributions and the central limit theorem

Normal distributions are an important family of symmetric, bell-shaped distributions, parametrized by mean μ and standard deviation σ .

They are so widely used *in statistics* because the distribution of a sample average will be approximately normal if the sample size is "large enough".

normal distributions and the central limit theorem

Normal distributions are an important family of symmetric, bell-shaped distributions, parametrized by mean μ and standard deviation σ .

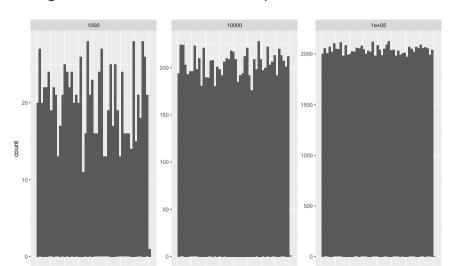

They are so widely used *in statistics* because the distribution of a sample average will be approximately normal if the sample size is "large enough".

"Large enough" is not fixed, but depends on the shape of the undelying population distribution, with more skewness requiring a larger sample size.

normal approximation illustration through simulation - I

I can simulate picking numbers uniformly at random between 0 and 1.

Here are histograms of 1000, 10000, and 100000 picks:

normal approximation illustration through simulation - II

I'll settle on k = 10000 "replications" of my simulation.

My simulation will actually consist of: * picking n numbers uniformly at random * calculating the average of those n numbers * doing this k times * making a histogram of the results.

I will choose n to be 2, 10, and 50.

normal approximation illustration through simulation - III
